CONTENTS

- 01** Our project
- 02** LEO satellites
- 03** Requirements

- 04** How it works
 - 01** Constellation creation
 - 02** Ground tracks plot
 - 03** PDOP computation
 - 04** Satellites Visibility Chart
- Focus on:
constellation selection

OUR PROJECT

SimuLEO is an innovative tool designed to simulate Low Earth Orbit (LEO) satellite orbits, offering a robust foundation for future positioning studies.

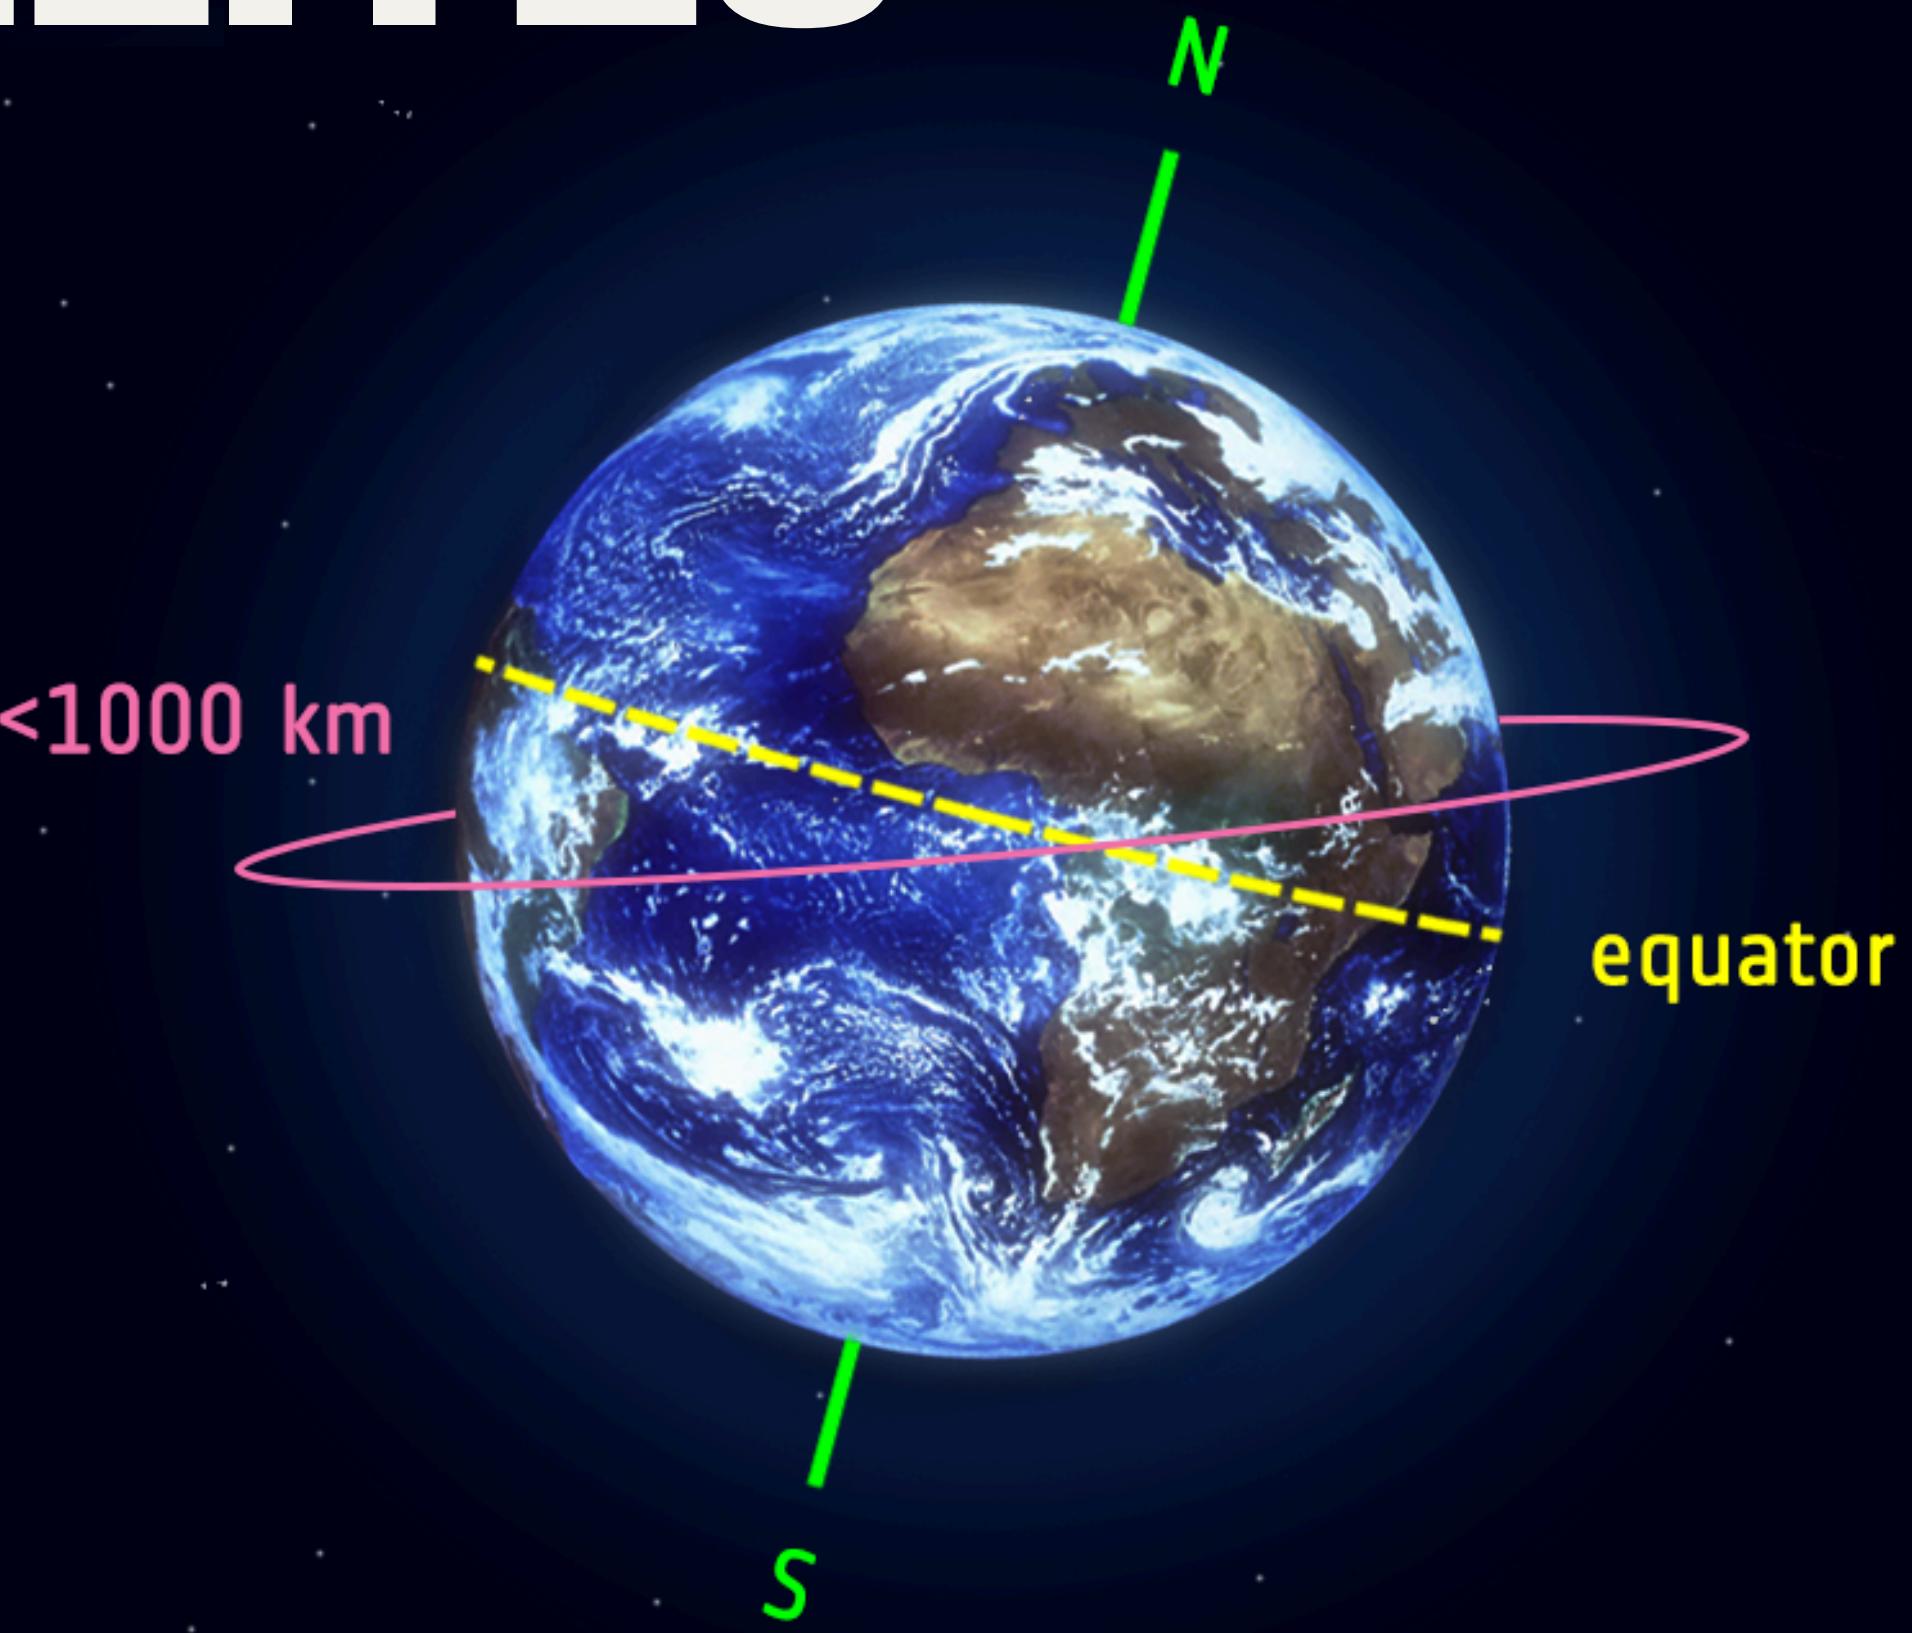

The tool comprises a user-friendly dashboard developed in Python (Jupyter Lab), allowing users to design satellite constellations and graphically represent the ground tracks and visibility charts, and allows PDOP computation.

The core computational work is handled by a group of functions written in Octave, responsible for accurately calculating satellite positions in the International Terrestrial Reference Frame (ITRF).

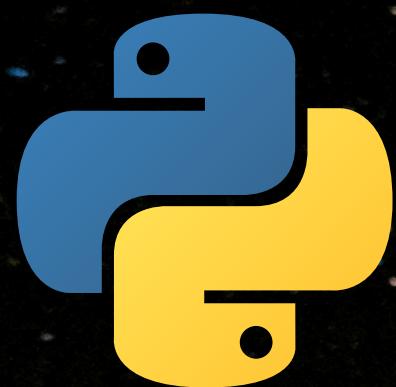

LEO SATELLITES

Low Earth Orbit (LEO) satellites are situated at altitudes lower than 1000 kilometers above the Earth's surface.

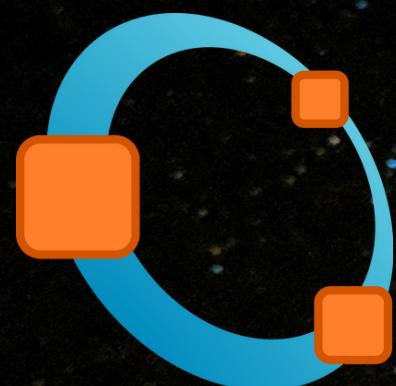

They are characterized by their rapid orbit times, often completing a full orbit in approximately 130 minutes. These satellites increasingly gain attention due to their potential to enhance global communication networks and positioning systems.

REQUIREMENTS

Python 3.11.5

GNU Octave 9.1.0

Libraries	
ipython 8.20.0	oct2py 5.6.1
ipywidgets 8.1.2	pandas 2.2.1
matplotlib 3.8.4	plotly 5.19.0
numpy 1.26.4	tk 8.6.12

HOW IT WORKS

01

Constellation
creation

02

Ground tracks
plot

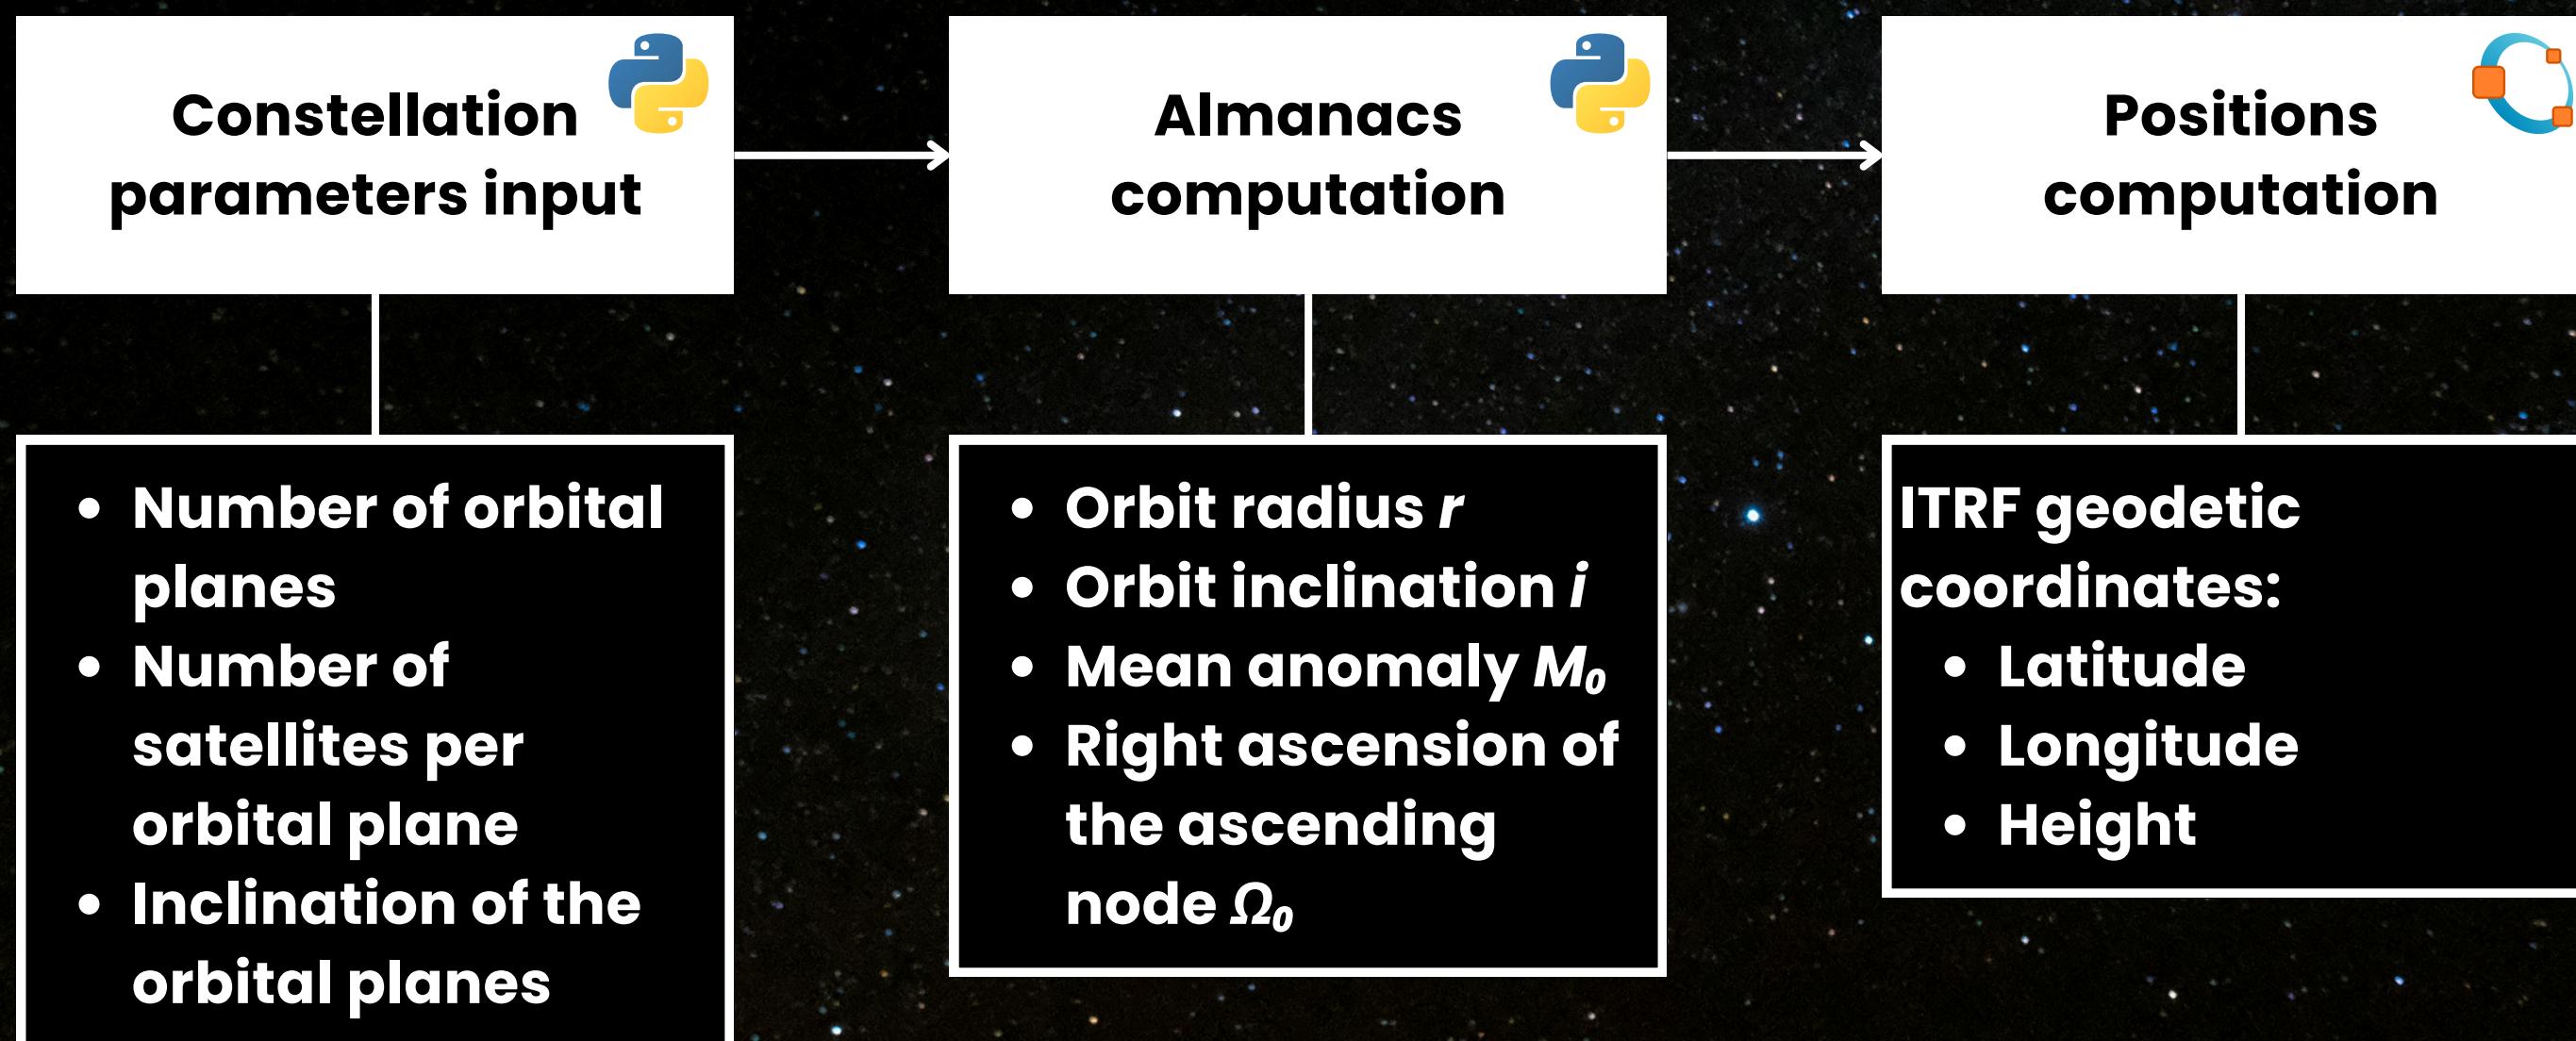

03

PDOP
computation

► FOCUS ON: CONSTELLATION SELECTION

Tkinter path selector

The different functionalities of the tool can be accomplished in sequence, or independently. In each step, the user selects a constellation from the saved designs to perform the chosen task.

Tkinter path selector allows the user to select the path of the constellation folder among the designed ones for which he/she wants to compute the task.

Thank you for the attention!
